The Anderson-Darling statistic is then computed using the linked equation above and the observed significance level (OSL) is computed using the linked equation above . This OSL measures the probability of observing an Anderson-Darling statistic at least as extreme as the value calculated if in fact the data are a sample from a lognormal distribution. If OSL < 0.05, one may conclude (at a five percent risk of being in error) that the population is not lognormally distributed. Otherwise, the hypothesis that the population is lognormally distributed is not rejected. For further information on these procedures, see reference 7.

Notes: The modified CV B-basis value is recommended when available.
 The CV provided corresponds with the B-basis value given.
 NA implies that tests were run but data did not meet NCAMP recommended requirements.
 "NA: A" indicates ANOVA with 3 batches, "NA: I" indicates insufficient data,
 Shaded empty boxes indicate that no test data is available for that property and condition.
 * Data is as measured rather than normalized
 ** indicates the Stat17 B-basis value is greater than 90% of the mean value.
