## **1. Introduction**

This report contains statistical analysis of ACG MTM45-1/GF0103-35%RW 7781 E glass fabric material property data published in “MTM45-1 GF0103 Data MH Cure Cycle Values Only 09-24-18.pdf” file. The lamina and laminate material property data have been generated with FAA oversight through FAA Special Project Number SP3505WI-Q, and retest material property data was generated with NCAMP oversight.

process known as equivalency. More information about this equivalency process including the test statistics and its limitations can be found in Section 6 of DOT/FAA/AR-03/19 and Section 8.4.1 of CMH-17 Rev G. The applicability of equivalency process must be evaluated on program-by-program basis by the applicant and certifying agency. The applicant and certifying agency must agree that the equivalency test plan along with the equivalency process described in Section 6 of DOT/FAA/AR-03/19 and Section 8.4.1 of CMH-17 Rev G are adequate for the given program.

Aircraft companies should not use the data published in this report without specifying NCAMP Material Specification NMS 451/4. NMS 451/4 has additional requirements that are listed in its prepreg process control document (PCD), fiber specification, fiber PCD, and other raw material

### 1.3 Basis Value Computational Process

The general form to compute engineering basis values is: basis value =  $\bar{X} - kS$  where  $k$  is a factor based on the sample size and the distribution of the sample data. There are many different methods to determine the value of  $k$  in this equation, depending on the sample size and the distribution of the data. In addition, the computational formula used for the standard deviation,  $S$  may vary depending on the distribution of the data. The details of those different computations and when each should be used are in section 2.0.

### 1.4 Modified Coefficient of Variation (CV) Method

A common problem with new material qualifications is that the initial specimens produced and tested do not contain all of the variability that will be encountered when the material is being produced in larger amounts over a lengthy period of time. This can result in setting basis values that are unrealistically high. The variability as measured in the qualification program is often lower than the actual material variability because of several reasons. The materials used in the qualification programs are usually manufactured within a short period of time, typically 2-3 weeks only, which is not representative of the production material. Some raw ingredients that are used to manufacture the multi-batch qualification materials may actually be from the same production batches or manufactured within a short period of time so the qualification materials, although regarded as multiple batches, may not truly be multiple batches so they are not representative of the actual production material variability.

The modified Coefficient of Variation (CV) used in this report is in accordance with section 8.4.4 of CMH-17 Rev G. It is a method of adjusting the original basis values downward in anticipation of the expected additional variation. Composite materials are expected to have a CV of at least 6%. The modified coefficient of variation (CV) method increases the measured coefficient of variation when it is below 8% prior to computing basis values. A higher CV will result in lower or more conservative basis values and lower specification limits. The use of the modified CV method is intended for a temporary period of time when there is minimal data available. When a sufficient number of production batches (approximately 8 to 15) have been produced and tested, the as-measured CV may be used so that the basis values and specification limits may be adjusted higher.

The material allowables in this report are calculated using both the as-measured CV and modified CV, so users have the choice of using either one. When the measured CV is greater than 8%, the modified CV method does not change the basis value. NCAMP recommended values make use the modified CV method when it is appropriate for the data.

When the data fails the Anderson-Darling K-sample test for batch to batch variability or when the data fails the normality test, the modified CV method is not appropriate and no modified CV basis value will be provided. When the ANOVA method is used, it may produce excessively conservative basis values.

In some cases a transformation of the data to fit the assumption of the modified CV resulted in the transformed data passing the ADK test and thus the data can be pooled only for the modified CV method.

NCAMP recommends that if a user decides to use the basis values that are calculated from as-measured CV, the specification limits and control limits be calculated with as-measured CV also. Similarly, if a user decides to use the basis values that are calculated from modified CV, the specification limits and control limits be calculated with modified CV also. This will ensure that the link between material allowables, specification limits, and control limits is maintained.

## **2. Background**

Statistical computations are performed with AGATE Statistical Analysis Program (ASAP) when pooling across environments is permissible according to CMH-17 Rev G guidelines. If pooling is not permissible, a single point analysis using STAT-17 is performed for each environmental condition with sufficient test results. If the data does not meet CMH-17 Rev G requirements for a single point analysis, estimates are created by a variety of methods depending on which is most appropriate for the dataset available. Specific procedures used are presented in the individual sections where the data is presented.

Where k refers to the number of batches and n<sub>i</sub> refers to the number of specimens in the i<sup>th</sup> sample

**2.1.2.2 Pooled Coefficient of Variation**

Since the mean for the normalized data is 1.0 for each condition, the pooled normalized data also has a mean of one. The coefficient of variation for the pooled normalized data is the pooled standard deviation divided by the pooled mean, as in equation 3. Since the mean for the pooled normalized data is one, the pooled coefficient of variation is equal to the pooled standard deviation of the normalized data.

Pooled Coefficient of Variation  $\frac{S_p}{1} = S_p$  Equation 5

**2.1.3 Basis Value Computations**

Basis values are computed using the mean and standard deviation for that environment, as follows: The mean is always the mean for the environment, but if the data meets all requirements for pooling, S<sub>p</sub> can be used in place of the standard deviation for the environment, S.

Basis Values:  $A \text{ basis } \bar{X}_a K_a S$  Equation 6  
 $B \text{ basis } \bar{X}_b K_b S$

**2.1.3.1 K-factor computations**

K<sub>a</sub> and K<sub>b</sub> are computed according to the methodology documented in section 8.3.5 of CMH-17 Rev G. The approximation formulas are given below:

$$K_a = \frac{2.3263}{\sqrt{q(f)}} \sqrt{\frac{1}{c_A(f) \tilde{n}_j} \frac{b_A(f)^2}{2 c_A(f)^2} - \frac{b_A(f)}{2 c_A(f)}} \quad \text{Equation 7}$$

$$K_b = \frac{1.2816}{\sqrt{q(f)}} \sqrt{\frac{1}{c_B(f) \tilde{n}_j} \frac{b_B(f)^2}{2 c_B(f)^2} - \frac{b_B(f)}{2 c_B(f)}} \quad \text{Equation 8}$$

Where

r = the number of environments being pooled together

n<sub>j</sub> = number of data values for environment j

$$N = \sum_{j=1}^r n_j$$

$$q(f) = 1 - \frac{2.323}{\sqrt{f}} - \frac{1.064}{f} - \frac{0.9157}{f\sqrt{f}} - \frac{0.6530}{f^2}$$

**Equation 9**

$$b_B(f) = \frac{1.1372}{\sqrt{f}} - \frac{0.49162}{f} + \frac{0.18612}{f\sqrt{f}}$$

**Equation 10**

$$c_B(f) = 0.36961 - \frac{0.0040342}{\sqrt{f}} + \frac{0.71750}{f} - \frac{0.19693}{f\sqrt{f}}$$

**Equation 11**

$$b_A(f) = \frac{2.0643}{\sqrt{f}} - \frac{0.95145}{f} + \frac{0.51251}{f\sqrt{f}}$$

**Equation 12**

$$c_A(f) = 0.36961 - \frac{0.0026958}{\sqrt{f}} + \frac{0.65201}{f} - \frac{0.011320}{f\sqrt{f}}$$

**Equation 13**

### 2.1.4.1 Transformation of data based on Modified CV

In order to determine if the data would pass the diagnostic tests under the assumption of the modified CV, the data must be transformed such that the batch means remain the same while the standard deviation of transformed data (all batches) matches the modified standard deviation.

To accomplish this requires a transformation in two steps:

Step 1: Apply the modified CV rules to each batch and compute the modified standard deviation  $S_j^*$   $CV^*$   $\bar{X}_j$  for each batch. Transform the data in each batch as follows:

$$X_{ij}^c = C_j \left( X_{ij} - \bar{X}_j \right) \frac{S_j^*}{S_j}$$

$$MNR = \frac{\max_{i=1, \dots, n} |X_i - \bar{X}|}{S} \tag{Equation 23}$$

$$C = \frac{n-1}{\sqrt{n}} \sqrt{\frac{t^2}{n-2-t^2}} \tag{Equation 24}$$

where t is the  $1 - \frac{.05}{2n}$  quartile of a t distribution with n - 2 degrees of freedom.

If  $MNR > C$ , then the  $X_i$  associated with the MNR is considered to be an outlier. If an outlier exists, then the  $X_i$  associated with the MNR is dropped from the dataset and the MNR procedure is applied again. This process is repeated until no outliers are detected. Additional information on this procedure can be found in references 1 and 2.

### 2.1.6 The k-Sample Anderson Darling Test for batch equivalency

The k-sample Anderson-Darling test is a nonparametric statistical procedure that tests the hypothesis that the populations from which two or more groups of data were drawn are identical. The distinct values in the combined data set are ordered from smallest to largest, denoted  $Z_{(1)}, Z_{(2)}, \dots, Z_{(L)}$ , where L will be less than n if there are tied observations. These rankings are used to compute the test statistic.

The k-sample Anderson-Darling test statistic is:

$$ADK = \frac{n-1}{n^2(k-1)} \sum_{j=1}^L \frac{1}{h_j} \left[ \sum_{i=1}^k \frac{F_{ij} - \eta H_j}{H_j} \right]^2 \frac{nh_j}{4} \tag{Equation 25}$$

Where

$n_i$  = the number of test specimens in each batch

$n = n_1 + n_2 + \dots + n_k$

$h_j$  = the number of values in the combined samples equal to  $Z_{(j)}$

$H_j$  = the number of values in the combined samples less than  $Z_{(j)}$  plus 1/2 the number of values in the combined samples equal to  $Z_{(j)}$

$F_{ij}$  = the number of values in the  $i^{th}$  group which are less than  $Z_{(j)}$  plus 1/2 the number of values in this group which are equal to  $Z_{(j)}$ .

The critical value for the test statistic at 1 -  $\alpha$  level is computed:

$$ADC_{1-\alpha} = 1 - \sqrt[n]{z_D} = \frac{0.678}{\sqrt{k-1}} - \frac{0.362\alpha}{k-1} \tag{Equation 26}$$

This formula is based on the formula in reference 3 at the end of section 5, using a Taylor's expansion to estimate the critical value via the normal distribution rather than using the t distribution with k-1 degrees of freedom.

**September 24, 2018**

**NCP-RP-2009-009 Rev A**

Where  $F_0$

10% Normal curve y-value:  $\max(v_{(i)} - 0.1, -1.1)$

**2.1.8.2 Normal Pearson’s r**

The Normal Pearson’s r statistic is the correlation coefficient of the actual data values with the predicted values computed assuming a normal distribution with the same mean and standard deviation as the original data and using the probability of survival as the percentile of the normal distribution.

Correlation Formula:  $r = \frac{1}{n-1} \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{S_x S_y}$  Equation 34

**2.1.9 Levene’s test for Equality of Coefficient of Variation**

Levene’s test performs an Analysis of Variance on the absolute deviations from their sample medians. The absolute value of the deviation from the median is computed for each data value.  $w_{ij} = |y_{ij} - y_j|$  An F-test is then performed on the transformed data values as follows:

$$F = \frac{\sum_{i=1}^k n_i \bar{w}_i^2 / (k-1)}{\sum_{i=1}^k \sum_{j=1}^{n_i} w_{ij}^2 / (n-k)}$$
 Equation 35

If this computed F statistic is less than the critical value for the F-distribution having k-1 numerator and n-k denominator degrees of freedom at the 1-α level of confidence, then the data is not rejected as being too different in terms of the co-efficient of variation. ASAP provides the appropriate critical values for F at α levels of 0.10, 0.05, 0.025, and 0.01. For more information on this procedure, see references 4 and 5.

**2.2 STAT-17**

This section contains the details of the specific formulas STAT-17 uses in its computations.

The basic descriptive statistics, the maximum normed residual (MNR) test for outliers, and the Anderson Darling K-sample test for batch variability are the same as with ASAP – see sections 2.1.1, 2.1.3.1, and 2.1.5.

Outliers must be dispositioned before checking any other test results. The results of the Anderson Darling k-Sample (ADK) Test for batch equivalency must be checked. If the data passes the ADK test, then the appropriate distribution is determined. If it does not pass the ADK test, then the ANOVA procedure is the only approach remaining that will result in basis values that meet the requirements of CMH-17 Rev G.

### 2.2.1 Distribution tests

In addition to testing for normality using the Anderson-Darling test (see 2.1.7); Stat-17 also tests to see if the Weibull or Lognormal distribution is a good fit for the data.

Each distribution is considered using the Anderson-Darling test statistic which is sensitive to discrepancies in the tail regions. The Anderson-Darling test compares the cumulative distribution function for the distribution of interest with the cumulative distribution function of the data.

An observed significance level (OSL) based on the Anderson-Darling test statistic is computed for each test. The OSL measures the probability of observing an Anderson-Darling test statistic at least as extreme as the value calculated if the distribution under consideration is in fact the underlying distribution of the data. In other words, the OSL is the probability of obtaining a value of the test statistic at least as large as that obtained if the hypothesis that the data are actually from the distribution being te

**2.2.2.1 One-sided B-basis tolerance factors, k**

Stat-17 solves these equations numerically for  $\hat{E}$  and  $\mathcal{L}$  in order to compute basis values.

### 2.2.2.3.2 Goodness-of-fit test for the Weibull distribution

The two-parameter Weibull distribution is considered by comparing the cumulative Weibull distribution function that best fits the data with the cumulative distribution function of the data. Using the shape and scale parameter estimates from section 2.2.2.3.1, let

$$z_i = x_i / \hat{\mathcal{L}}^{\hat{E}}, \text{ for } i = 1, \dots, n \quad \text{Equation 41}$$

V is the value in Table 2-2. when the sample size is less than 16. For sample sizes of 16 or larger, a numerical approximation to the V values is given in the two equations immediately below.

$$V_B = 3.803 \left[ \exp \left( 1.79 - 0.516 \ln(n) \right) \frac{5.1^a}{n - 1} \right] \quad \text{Equation 48}$$

$$V_A = 6.649 \left[ \exp \left( 2.55 - 0.526 \ln(n) \right) \frac{4.76^a}{n - 1} \right] \quad \text{Equation 49}$$

This approximation is accurate within 0.5% of the tabulated values for n greater than or equal to 16.

Weibull Dist. K Factors for N<16		
N	B-basis	A-basis
2	690.804	1284.895
3	47.318	88.011
4	19.836	36.895
5	13.145	24.45
6	10.392	19.329

14	5.992	11.098
15	5.875	10.861

Table 2-2: Weibull Distribution Basis Value Factors

**2.2.2.4 Lognormal Distribution**

A probability distribution for which the probability that an observation selected at random from this population falls between a and b  $0 < a < b$  is given by the area under the normal distribution between  $\ln(a)$  and  $\ln(b)$ .

The lognormal distribution is a positively skewed distribution that is simply related to the normal distribution. If something is lognormally distributed, then its logarithm is normally distributed. The natural (base e) logarithm is used.

**2.2.2.4.1**

$$z_i = \frac{\ln x_i - \bar{x}_L}{s_L}, \text{ for } i = 1, \dots, n$$

Equation 50

where  $x$

The formula for the A-basis values should be rounded to the nearest integer. This approximation is exact for most values and for a small percentage of values (less than 0.2%), the approximation errs by one rank on the conservative side.

### 2.2.5.1 Calculation of basis values using ANOVA

The following calculations address batch-to-batch variability. In other words, the only grouping is due to batches and the k-sample Anderson-Darling test (Section 2.1.6) indicates that the batch to batch variability is too large to pool the data. The method is based on the one-way analysis of variance random-effects model, and the procedure is documented in reference 10.

ANOVA separates the total variation (called the sum of squares) of the data into two sources: between batch variation and within batch variation.

First, statistics are computed for each batch, which are indicated with a subscript  $n_i, \bar{x}_i, s_i^2$  while statistics that were computed with the entire dataset do not have a subscript. Individual data values are represented with a double subscript, the first number indicated the batch and the second distinguishing between the individual data values within the batch.  $k$  stands for the number of batches in the analysis. With these statistics, the Sum of Squares Between batches

Denote the ratio of mean squares by

$$u = \frac{MSB}{MSE} \tag{Equation 62}$$

If u is less than one, it is set equal to one. The tolerance limit factor is

$$T = \frac{k_0 \frac{k_1}{\sqrt{nc}} + k_1 k_b \sqrt{\frac{u}{u + nc - 1}}}{1 + \frac{1}{\sqrt{nc}}} \tag{Equation 63}$$

The basis value is  $\bar{X} - TS$ .

The ANOVA method can produce extremely conservative basis values when a small number of batches are available. Therefore, when less than five (5) batches are available and the ANOVA method is used, the basis values produced will be listed as estimates.

### 2.3 Single Batch and Two Batch estimates using modified CV

This method has not been approved for use by the CMH-17 organization. Values computed in this manner are estimates only. It is used only when fewer than three batches are available and no valid B-basis value could be computed using any other method. The estimate is made using the mean of the data and setting the coefficient of variation to 8 percent if it was less than that. A modified standard deviation ( $S_{adj}$ ) was computed by multiplying the mean by 0.08 and computing the A and B-basis values using this inflated value for the standard deviation.

$$\text{Estimated B-Basis} = \bar{X} - k_b S_{adj} = \bar{X} - k_b (0.08 \bar{X}) \tag{Equation 64}$$

### 2.4 Lamina Variability Method (LVM)

This method has not been approved for use by the CMH-17 organization. Values computed in this manner are estimates only. It is used only when the sample size is less than 16 and no valid B-basis value could be computed using any other method. The prime assumption for applying the LVM is that the intrinsic strength variability of the laminate (small) dataset is no greater than the strength variability of the lamina (large) dataset. This assumption was tested and found to be reasonable for composite materials as documented by Tomblin and Seneviratne [12].

To compute the estimate, the coefficients of variation (CVs) of laminate data are paired with lamina CV's for the same loading condition and environmental condition. For example, the 0° compression lamina CV CTD condition is used with open hole compression CTD condition. Bearing and in-plane shear laminate CV's are paired with 0° compression lamina CV's. However, if the laminate CV is larger than the corresponding lamina CV, the larger laminate CV value is used.

### **3. Summary of Results**

The basis values for all tests are summarized in the following tables. The recommended B-basis values all meet the requirements of CMH-17 Rev G, and are compiled in Table 3-1 and Table 3-2. However, not all test data meets those requirements. All basis values

#### **4. Lamina Test Results, Statistics, Basis Values and Graphs**

Test data for fiber dominated properties was normalized according to nominal cured ply thickness. Both normalized and as measured statistics were included in the tables, but only the normalized data values were graphed. Test failures, outliers and explanations regarding computational choices were noted in the accompanying text for each test.

All individual specimen results are graphed for each test by batch and environmental condition with a line indicating the recommended basis values for each environmental condition. The data is jittered (moved slightly to the left or right) in order for all specimen values to be clearly visible. The strength values are always graphed on the vertical axis with the scale adjusted to include all data values and their corresponding basis values. The vertical axis may not include zero. The horizontal axis values will vary depending on the data and how much overlapping there was of the data within and between batches. When there was little variation, the batches were graphed from left to right and the environmental conditions were identified by the shape and color of the symbol used to plot the data. Otherwise, the environmental conditions were graphed from left to right and the batches were identified by the shape and color of the symbol.

When a dataset fails the Anderson-Darling k-sample (ADK) test for batch-to-batch variation an ANOVA analysis is required. In order for B-basis values computed using the ANOVA method, data from five batches is required. Since this qualification dataset has only three batches, the basis values computed using ANOVA are considered estimates only. However, the basis values resulting from the ANOVA method using only three batches may be overly conservative. The ADK test is performed again after a transformati

#### **4.1 Warp (0°) Tension Properties (WT)**

The RTD (both as measured and normalized) and the ETW2 (as measured only) datasets passed the Anderson-Darling k-sample test (ADK test) for batch-to-batch variation. The remaining datasets required the ANOVA method to compute basis values, which may result in overly conservative estimates of the basis values.

The normalized ETW and ETW2 data passes the ADK test with the modified CV transformation,

**September 24, 2018**

**NCP-RP-2009-009 Rev A**

## 4.2 Fill (90°) Tension Properties (FT)

For the normalized data, all environments pass both the normality test and the ADK test, but the pooled dataset did not pass the normality test, so pooling all four environments was not appropriate. Only the CTD and RTD environments could be pooled together.

For the as measured data, the ETW environment did not pass the Anderson-Darling k-sample test for batch-to-batch variation. That dataset required the ANOVA method to compute basis values, which may result in overly conservative estimates of the basis values. Only the CTD and RTD environments could be pooled. The ETW data passed the ADK test with the modified CV transformation, so all four environments could be pooled for the modified CV basis values.

There were a total of four outliers in the normalized data. There were two outliers before pooling batches, RTD batch 3 and ETW2 batch 2, both on the low side. There were another two outliers after pooling batches, one each in ETW and ETW2, both in batch one and both on the low side. All outliers were retained for this analysis. There were no outliers in the as measured data.

Statistics, estimates and basis values are given

#### **4.5 In-Plane Shear Properties (IPS)**

In the 5% strain strength data, there were insufficient specimens in the CTD, RTD, and ETW2 environments to produce B-basis values that meet all CMH-17 Rev G requirements for publication, so only estimates of the basis values are available. The ETW data failed the ADK initially, but passes with the modified CV transform, so modified CV basis values are provided

## 5. Laminate Test Results, Statistics and Basis Values

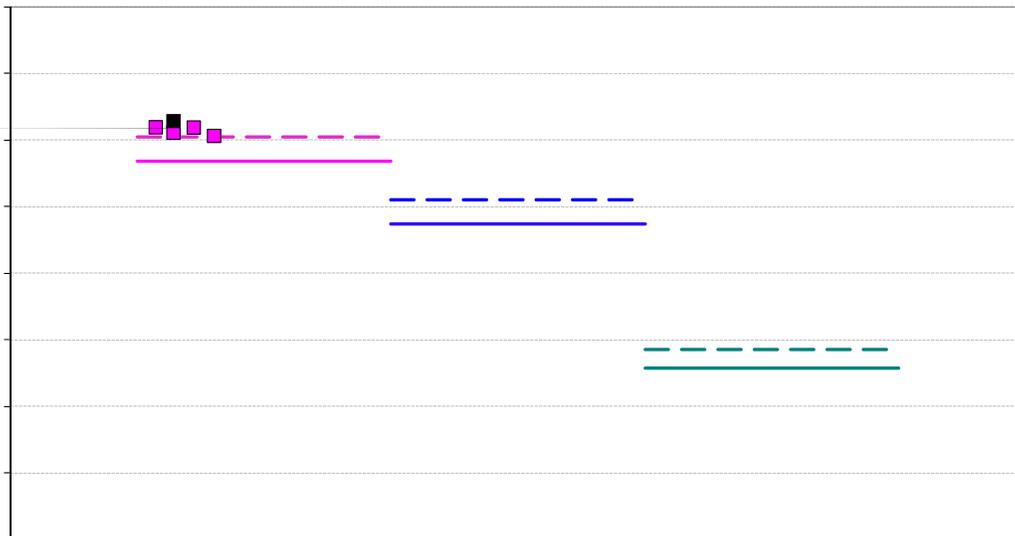

Some laminate tests were performed with one batch only. This is insufficient data to produce basis values that meet the requirements of CMH-17 Rev G, so only estimates are provided. Estimates were prepared using the lamina variability method documented in section 2.4 or by pooling with the other environments when appropriate. The more conservative of the LVM or pooled estimate was provided.

### 5.1 Quasi Isotropic Unnotched Tension (UNT1) Properties

The UNT1 data was pooled across the three environments. The ETW2 environment has only seven specimens available, so estimates only are provided. The ETW2 data was included in the pooled dataset, but because the LVM estimate was more conservative, the LVM estimate is provided. For the modified CV approach, the pooled estimate was more conservative than the LVM estimate, so the pooled estimate is provided as the ETW2 Mod CV estimate.

There was one outlier. It was on the high side of batch three in the CTD environment for the as measured data only. It was an outlier both before and after pooling. It was retained for this analysis.

Statistics, estimates and basis values are given for the UNT1 strength data in Table 5-1. Statistics for the modulus data are given in Table 5-2. The normalized data, B-estimates and B-basis values are shown graphically in Figure 8.

## 5.2 Quasi Isotropic Un-notched Compression (UNC1) Properties

The RTD and ETW2 datasets did not pass the ADK test even with the modified CV transform. They required the ANOVA method to compute basis values which may result in overly conservative estimates of the basis values. Estimates were computed using the modified CV method. These are termed estimates due to the failure of the ADK test after the transformation for the modified CV method. Pooling was used to compute the Mod CV estimates.

There were no outliers. Statistics, A- and B-estimates are given for the UNC1 normalized strength data in Table 5-3. Statistics for the modulus data are given in Table 5-4. The normalized data and B-estimates are shown graphically in Figure 9.

## 5.7 Quasi Isotropic Filled Hole Compression (FHC1) Properties

There was insufficient data to produce any basis values that would not be considered estimates. The FHC1 ETW2 data did not pass the normality test. The lognormal distribution was the best fit. There were no outliers. Statistics and A- and B-estimates are given for the FHC1 strength data in Table 5-13. The normalized data and B-estimates are shown graphically in Figure 18.

## 6. Outliers

Outliers were identified according to the standards documented in section 2.1.5, which are in accordance with the guidelines developed in CMH-17 Rev G section 8.3.3. An outlier may be an outlier in the normalized data, the as measured data, or both. A specimen may be an outlier for the batch only (before pooling the three batches within a condition together) or for the condition (after pooling the three batches within a condition together) or both.

Approximately 5 out of 100 specimens will be iden
